# Conflicts of Interest

CRISPR Therapeutics: Equity and SAB

Managed through Stanford in accordance with their conflict of interests policy.

# Take Home Points

1. There are thousands of diseases that affect only a small number of patients and establishing a burdensome regulatory path that is not based on scientific risk will inhibit genome editing based therapies being developed.
2. Current clinically relevant methods of genome editing using the CRISPR/Cas9 platform *ex vivo* are highly specific (more specific than life).
3. Bioinformatic methods identify the relevant off-target sites using clinically relevant delivery methods.
4. There are no validated animal models to predict in human genotoxicity for genome editing.
  - Standard NSG mouse xenograft models do not support most human blood cancers (Reinisch et al Nature Medicine (2016) PMID 27213817)
5. Translocations between the on-target break and spontaneous breaks will occur but at a frequency that is too low to be detected by current methods.
6. The best test of the safety of genome editing based therapeutics is phase I trials for serious diseases with unmet medical needs with reasonable follow-up.

# Genotoxicity vs functional toxicity

**Peter Marks (head of CBER, FDA): “We don’t want off-target events leading to serious adverse events.”**

**Implication: Off-target changes *per se* are not serious adverse events—only if they lead to functional adverse events.**

**48 other potential off-target sites were analyzed with no evidence of INDELS in CD34+ HSPCs modified by RNP**

*with Ciaran Lee and Gang Bao (Rice University)*

# Ex vivo Genome Editing is More Precise than Life

- **Tremendous genetic diversity among humans to begin with:**  
Baseline Variation Per Person: 2.4 million SNVs, 500-600K In/Dels (355 Exonic, 91 Frameshift), ~3000 structural variants (i.e. Dewey et al 2014 JAMA)
- **Tremendous ongoing genetic diversity within each person**  
10-20 new mutations per every cell division

Assumes high fidelity of DSB Repair: 90% (9 out of 10 breaks are repaired precisely)

# Proposed Standards

- 1. Analysis of potential off-target INDELS should be performed at all potential off-target sites in which there are 3 or fewer mismatches (excluding nucleotide 20) and no PAM mismatches identified bio-informatically using the delivery method and cell type that is part of the target product profile (TPP).**
  - Other techniques can supplement but not replace this analysis of potential off-target sites.**
- 2. If on-target site or off-target sites with known INDELS are not associated with cancers (for the tissue type that might be modified), then no further genotoxicity/tumorigenicity studies need to be performed.**
- 3. If on-target site or off-target sites with known INDELS are associated with cancers (for the tissue type that might be modified), then thoughtful functional assays for genotoxicity/tumorigenicity should be performed.**
- 4. Samples from patients treated with genome edited therapeutics should be archived (15 years?) for analysis if genotoxicity/tumors occur.**

# Thank You
