

GOOD PEOPLE, BAD DECISIONS: AN INTERPLAY OF ECONOMICS, PSYCHOLOGY AND RISK

Dmitry Zhdanov. NIST NICE Workshop 2013

Causes of (in)security in decisions

- Cognitive limitations
 - Rewards and outcomes
 - It's all about risk
 - Garbage in, garbage out
-
- What to do?

It's all in your head

Let's look at the individuals first

Houston, we have a problem

- ❑ Users do not think they are at risk
- ❑ Users aren't stupid, they are unmotivated
- ❑ Safety is an abstract concept
- ❑ Feedback and learning from security-related decisions is weak

Houston, we have a problem

- Making trade-offs between risk, losses, gains and costs
- Users are more likely to gamble on a loss than accept a guaranteed loss
- Losses are perceived disproportionately to gains
- Security is a secondary task

Users do not think they are at risk

- People tend to believe that they are less vulnerable than others. This includes a wide range of scenarios from consumer products to health to computer security
 - ▣ Thus, why patch/firewall/antivirus...? Nothing bad can happen

Users aren't stupid, they are unmotivated

- Cognitive miser = limited capacity for information processing
 - ▣ Thus, multitask and rely on heuristics..
 - ... which bring good outcomes *MOST* of the time
 - What do you do when a warning pop-up shows on the screen?

Safety is an abstract concept

- Concrete outcomes dominate abstract
 - ▣ Yet, “secure” choice frequently has no visible outcome or visible threat
 - ▣ Thus, click that link!
- Also, fall back on the heuristics

Feedback and learning

- Typical learning: do something right, get a reward.
Do something wrong, get a penalty
- Security: do something right, and nothing bad happens
- Security: do something wrong, and the negative impact is not immediate or direct
 - ▣ Thus, learning of consequences is difficult

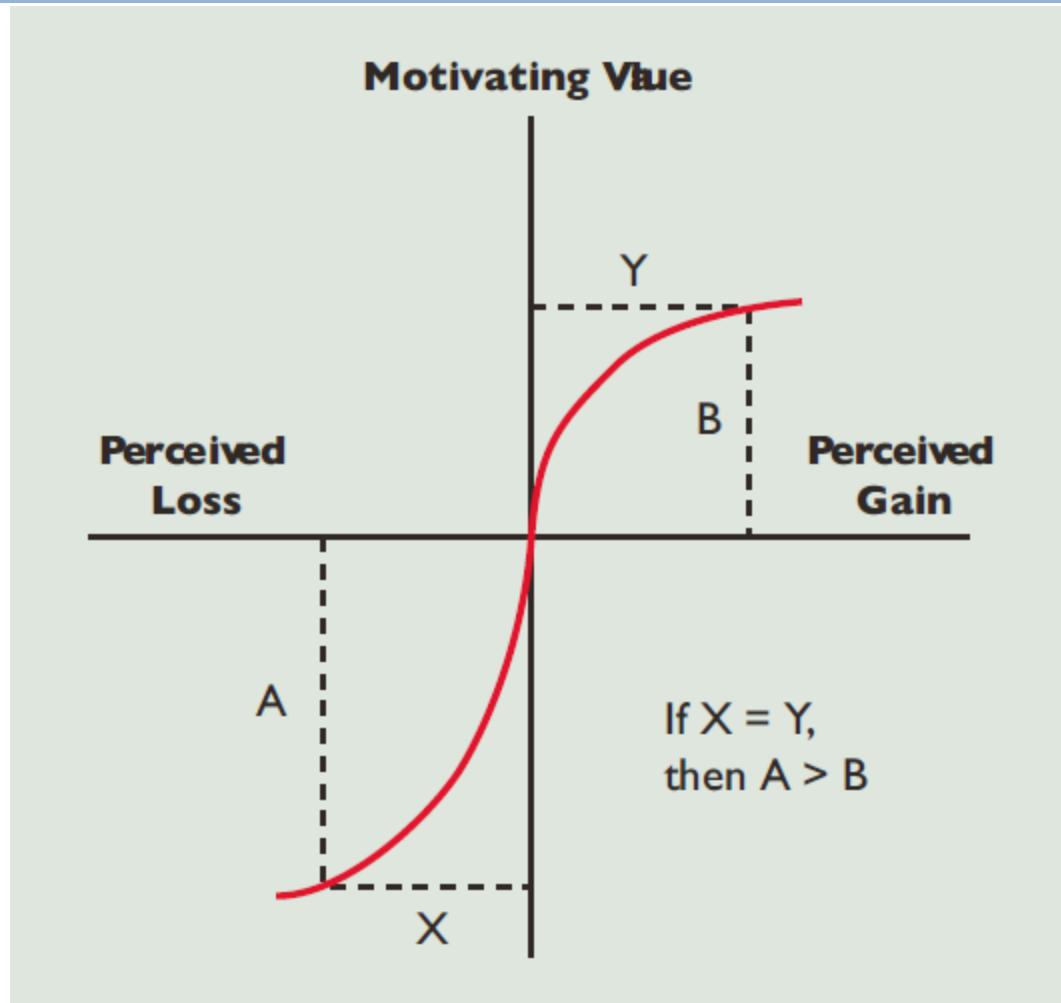

Gain\loss tradeoffs

- Scenario 1: guaranteed GAIN of \$5 versus a coin toss with the outcomes \$0, \$10

Gain\loss tradeoffs

- Scenario 2: guaranteed LOSS of \$5 versus a coin toss with the outcomes \$0, -\$10

Gain\loss tradeoffs

R. West "The Psychology of Security", 2008 (CACM)

Other factors of gains\losses

- Scale – people do not conceptualize very large or very small magnitudes well
- Probability – generally hard to estimate, but the magnitude is also a problem (particularly small one)

Look out!

- Average number of deaths in a year caused by...

Look out!

- Average number of deaths in a year caused by...

<1

- Average number of deaths in a year caused by...

53

Look out!

- Average number of deaths in a year caused by...

Look out!

- Average number of deaths in a year caused by...

130

Yet, who are we afraid of?

Security is a secondary task

- When under time pressure, people tend to focus more on the losses affecting their immediate task
 - ▣ Thus, take shortcuts, ignore policies, etc.

Losses perceived disproportionately

- When users perceive a gain and a loss to have the same value, loss is actually more motivating
 - ▣ Thus, even if the cost of security effort is “small”, it may seem worse for the users

Conditional probability

THE ANNUAL DEATH RATE AMONG PEOPLE WHO KNOW THAT STATISTIC IS ONE IN SIX.

Got brakes?

- Munich Taxi study (early 1980s)
- Used ABS brakes on 50% of cabs
- Accelerometers installed unknown to drivers

- Results:
 - ▣ No significant difference in accident rates
 - ▣ Cabs with ABS were driven more aggressively (acceleration, harsh stops)
- <http://www.drivers.com/article/411>

A driving lesson

- British study: accidents by type of training
 - A. Driving school only
 - B. With friends or relatives only
 - C. Combined training

- Atlanta, DeKalb County, Georgia - similar variation by the number of training hours (Safe Performance Curriculum, basic training, no formal training)

A driving lesson

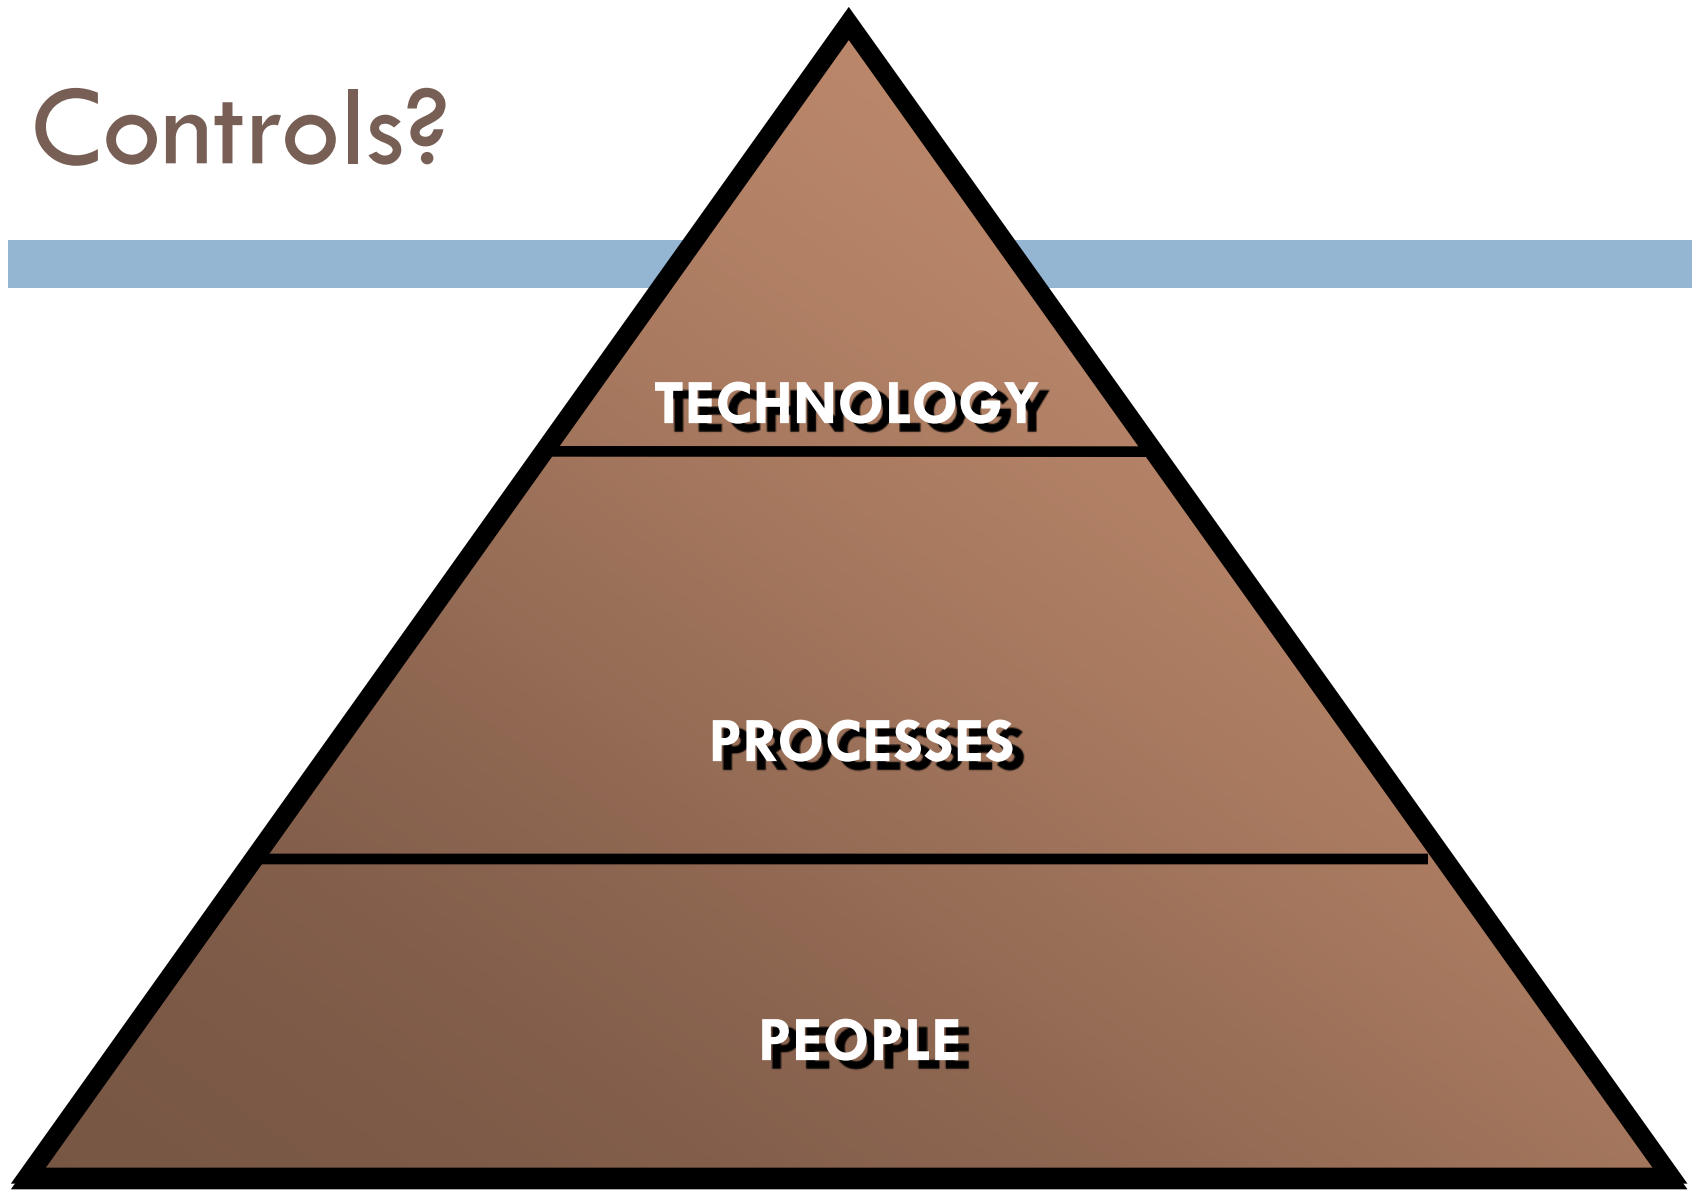

- British study: results (km driven per accident)
 - A. 19,392
 - B. 22,801
 - C. 14,536

- Atlanta, DeKalb County, Georgia
 - ▣ No significant difference in crashes for minimal training or no formal training
 - ▣ MORE accidents for SPC

Risk Homeostasis Theory

- In all activities, people balance subjective estimates of risk with the benefits they are hoping to receive
- There may be such thing as “too little risk”
 - ▣ i.e., “optimal” risk level is not equal to zero

Controls?

Fundamentally, only **THREE** countermeasures are available to protect critical information infrastructures.

Solutions

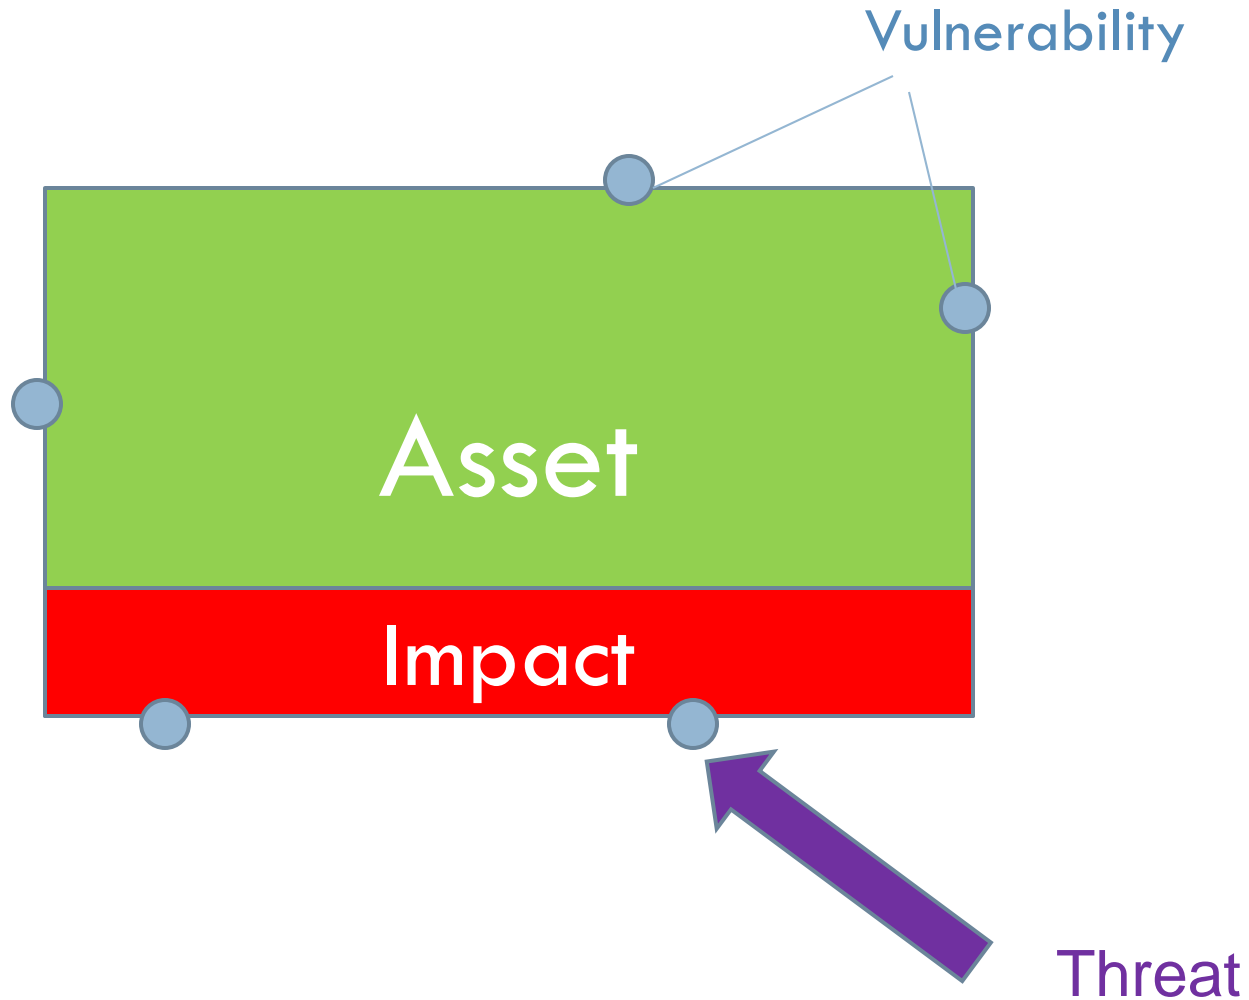

- Technical
 - ▣ Doesn't look like it's working – from ABS to antivirus
- Policies/processes (enforcement)
 - ▣ Sometimes it's working, if the rewards are positive
 - ▣ Beware of reactance; reciprocity
- People-oriented (education)
 - ▣ Sometimes it's working, if it focuses on positive reinforcement and simple messages
 - ▣ Beware of building overconfidence

Strength in numbers

Corporate decision making

Risk Management

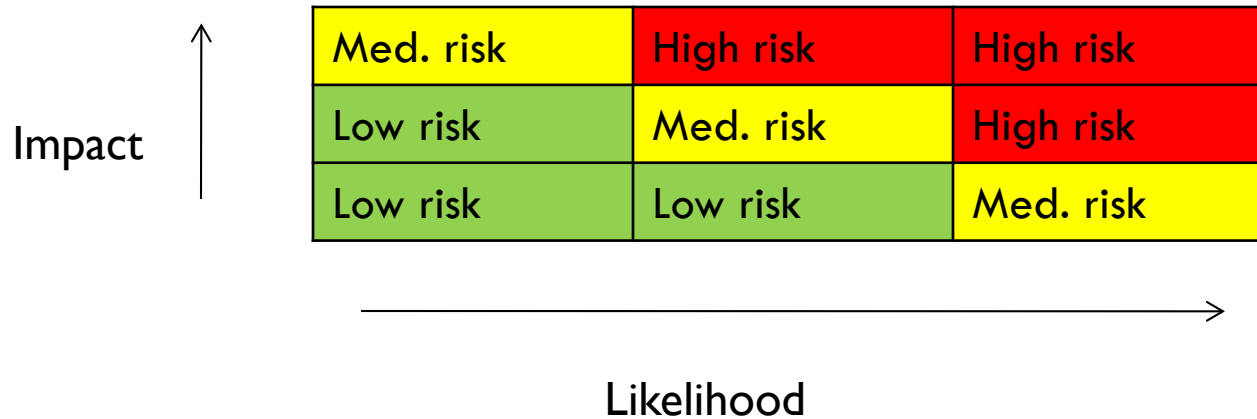

Ways of dealing with risk

- Accept
 - ▣ “Do nothing” – does not mean being oblivious to risk!
- Transfer
 - ▣ Legal agreement, insurance, pooling arrangements
- Mitigate
 - ▣ Implement countermeasures yourself

Qualitative versus Quantitative Risk Assessment

- It is impossible to conduct risk management that is purely quantitative.
- Usually risk management includes both qualitative and quantitative elements, requiring both analysis and judgment or experience.
- It is possible to accomplish purely qualitative risk management.

Qualitative risk assessment

Quantitative risk assessment

□ $ALE = ARO \times SLE$

■ $SLE = AV \times EF$

- $ALE =$ Annualized loss expectancy
- $ARO =$ Annual rate of occurrence
- $SLE =$ Single loss expectancy
- $AV =$ Asset value
- $EF =$ Exposure factor

Is there something wrong with this approach?

Economics, rationality and risk

- What is “economic rationality”?
- What is “rational” attitude towards risk?
- Alternative theories of risk
 - ▣ Value at risk
 - ▣ Ruin theory
 - ▣ Info-gap decision theory

Meanwhile, on the dark side...

Black market at work

Zeus

- Accounted for about 50% of all financial information stolen in 2009-2010
- Basic configuration tool sold for \$700, versions with updates(!) and support(!!!!) sold for up to \$15,000
- Highly customizable
- 55% of infected machines had up-to-date antivirus (effective detection rate of 23% - Trusteer 2009)

Cyber Theft Ring

Malware exploiters purchase malware and use it to steal victim banking credentials. They launch attacks from compromised machines that allow them to transfer stolen funds and deter any tracking of their activities.

Money mule networks are comprised of individuals engaged in the transfer of stolen funds who retain a percentage for their services.

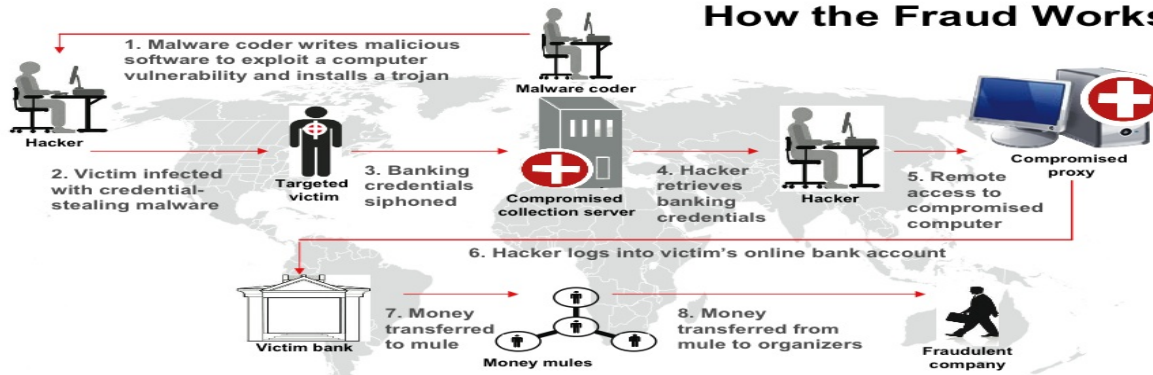

Victims include individuals, businesses, and financial institutions.

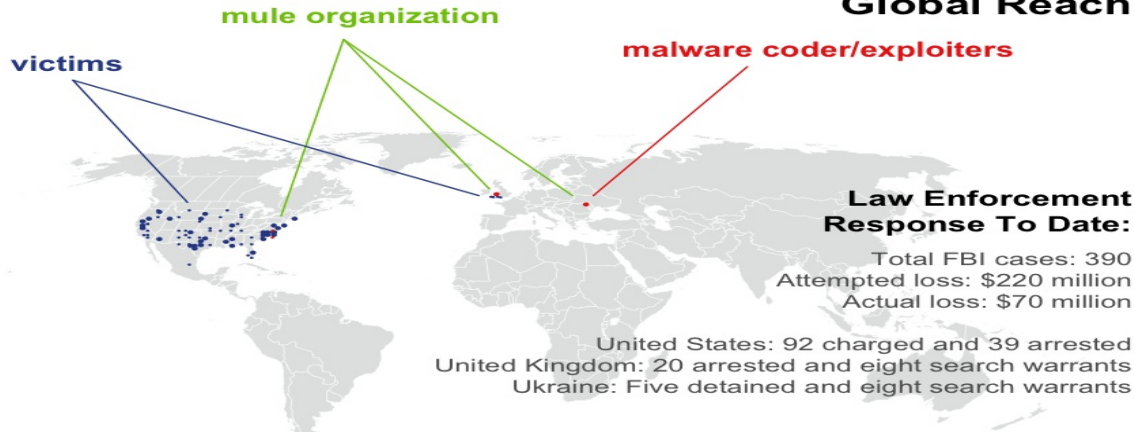

Malware coders develop malicious software that is sold on the black market.

How the Fraud Works

Global Reach

Law Enforcement Response To Date:

Total FBI cases: 390
 Attempted loss: \$220 million
 Actual loss: \$70 million

United States: 92 charged and 39 arrested
 United Kingdom: 20 arrested and eight search warrants
 Ukraine: Five detained and eight search warrants

Source: FBI, via Wikipedia

Zeus is dead? All hail SpyEye!

- Competition between trojans
- Zeus writer announced “retirement” in Oct. 2010
- Word was that SpyEye writers bought out Zeus
- Zeus source code leaked to public in May’11

- In March 2011, there were 230 verified SpyEye C&C servers, 25 with files online
- Average detection rate by antivirus is 29.72% (malwarehelp.org)

Evolution of Zeus and SpyEye

- Variants for Android, Blackberry platforms
- Capable of bypassing two-factor authentication (e.g., via intercept of text messages)
- Intercepting bank web pages and presenting fake account balances in the browser

Thank you!
